

# Vernier scans RHC run22

## Online (“lisa”):

- No singles correction
- Only 1G fit
- Using model “bump”

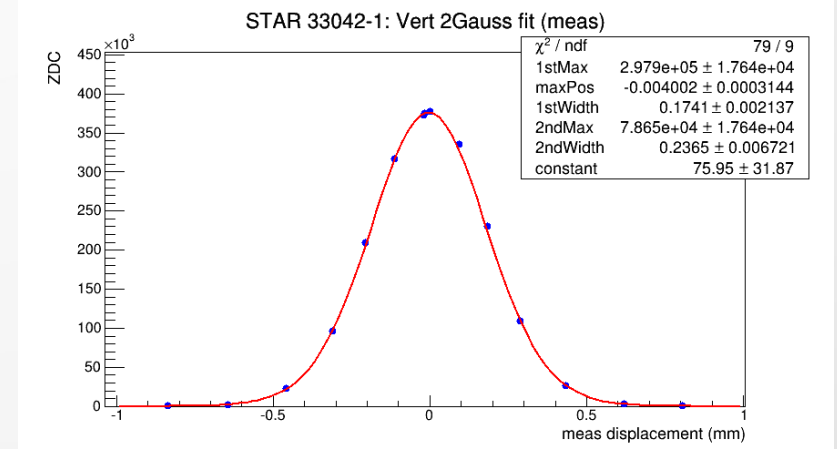

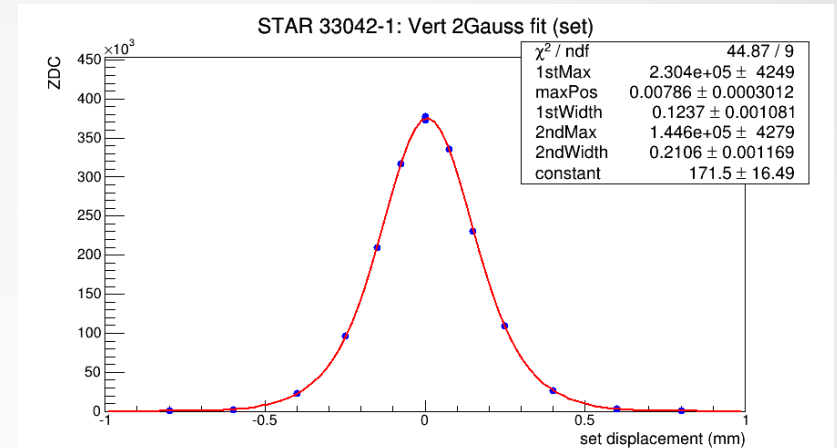

## Offline:

- Singles correction
- 2G or 2G+const fit
- Model or BPM
- Moving ring only
- Both rings

## Total of 14 scans

- High and low intensity
- 28-111 bunches
- Gain x1 and x10
- Blue and Yellow
- 3 different ramps

# 33042 #1, 111x111 beta\* 1.2 m, Y

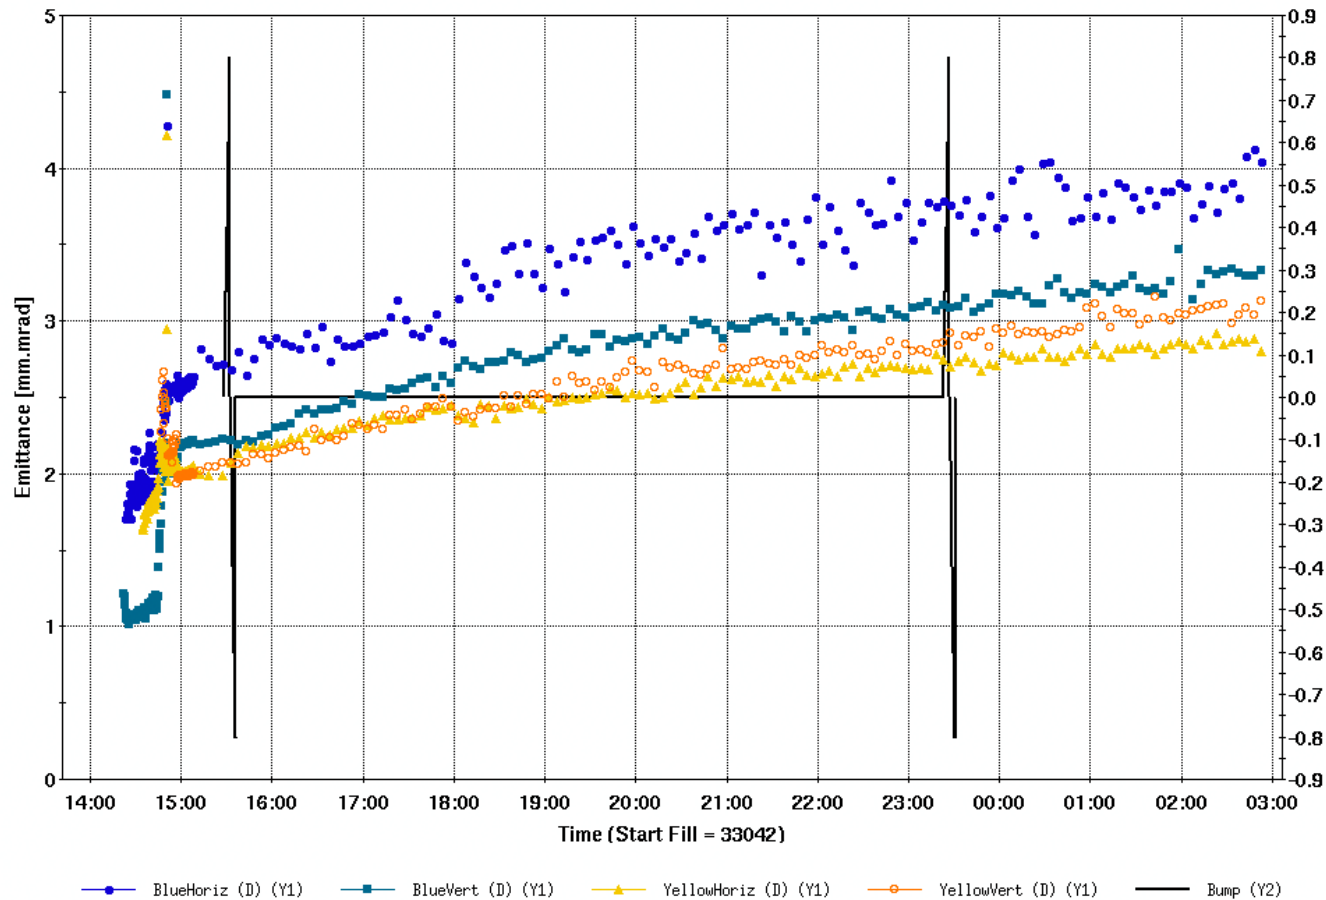

Model (set) fits typically have better  $\chi^2$

# 33042 #2, 111x111, beta\* 1.0 m, Y

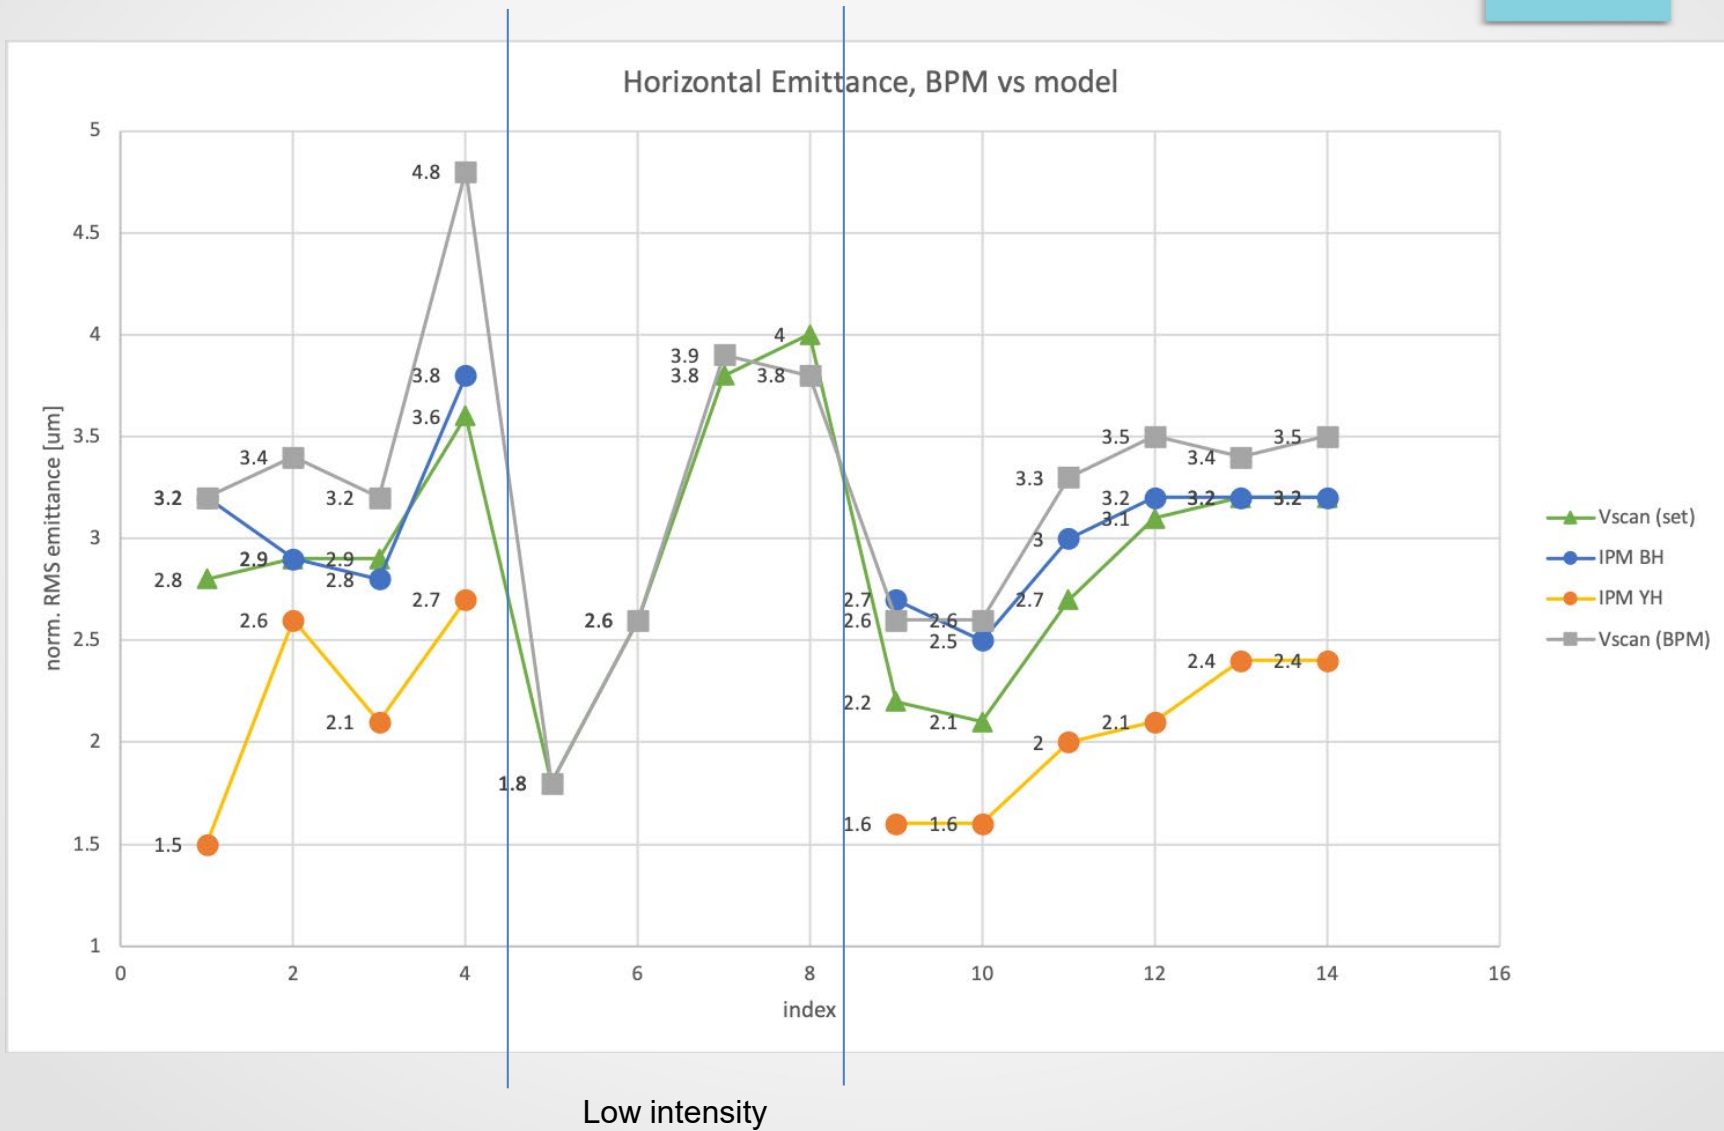

Discrepancy between model and set is evident regardless of rampfile

# Comparison vscan with IPM emittance

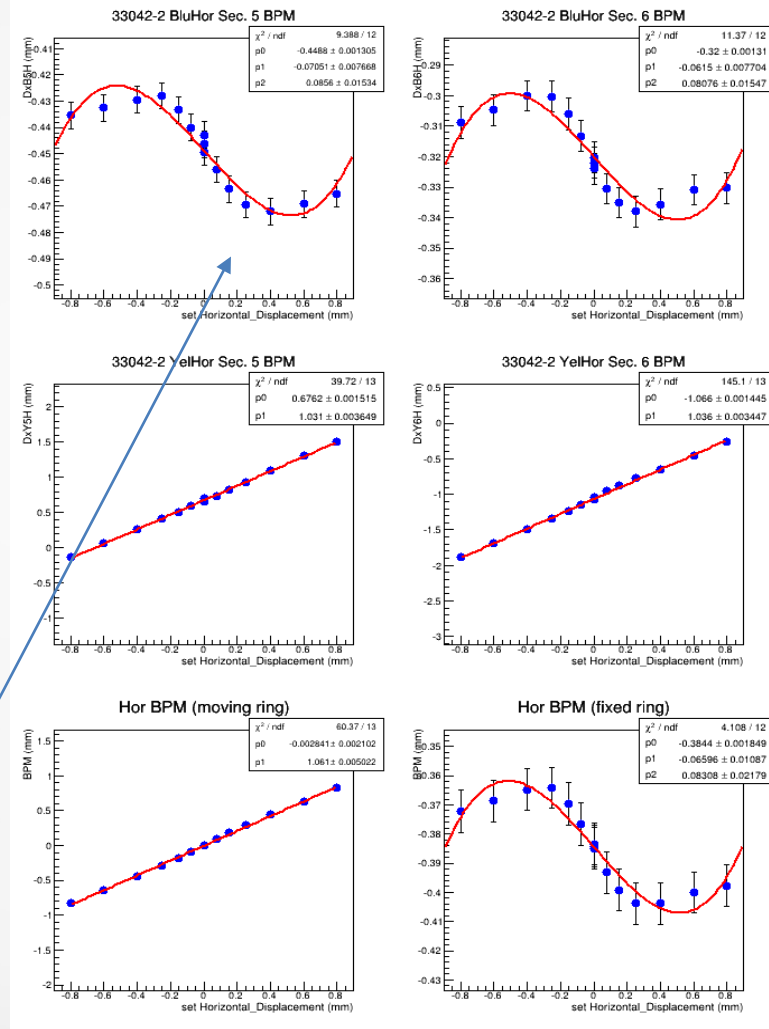

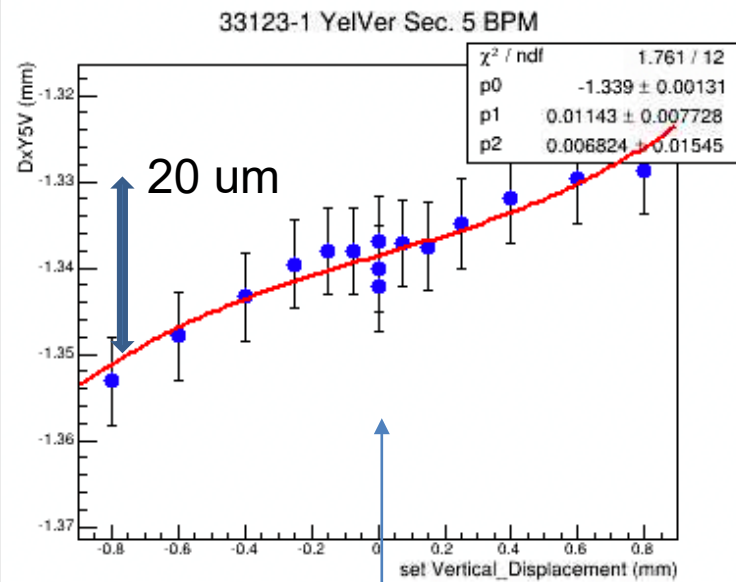

IPM scatter is rather large  
Blue is typically larger than yellow  
Expect vscan results between blue and yellow

# IPM and vscan (Hor)

# Beam-beam or electronic cross talk?

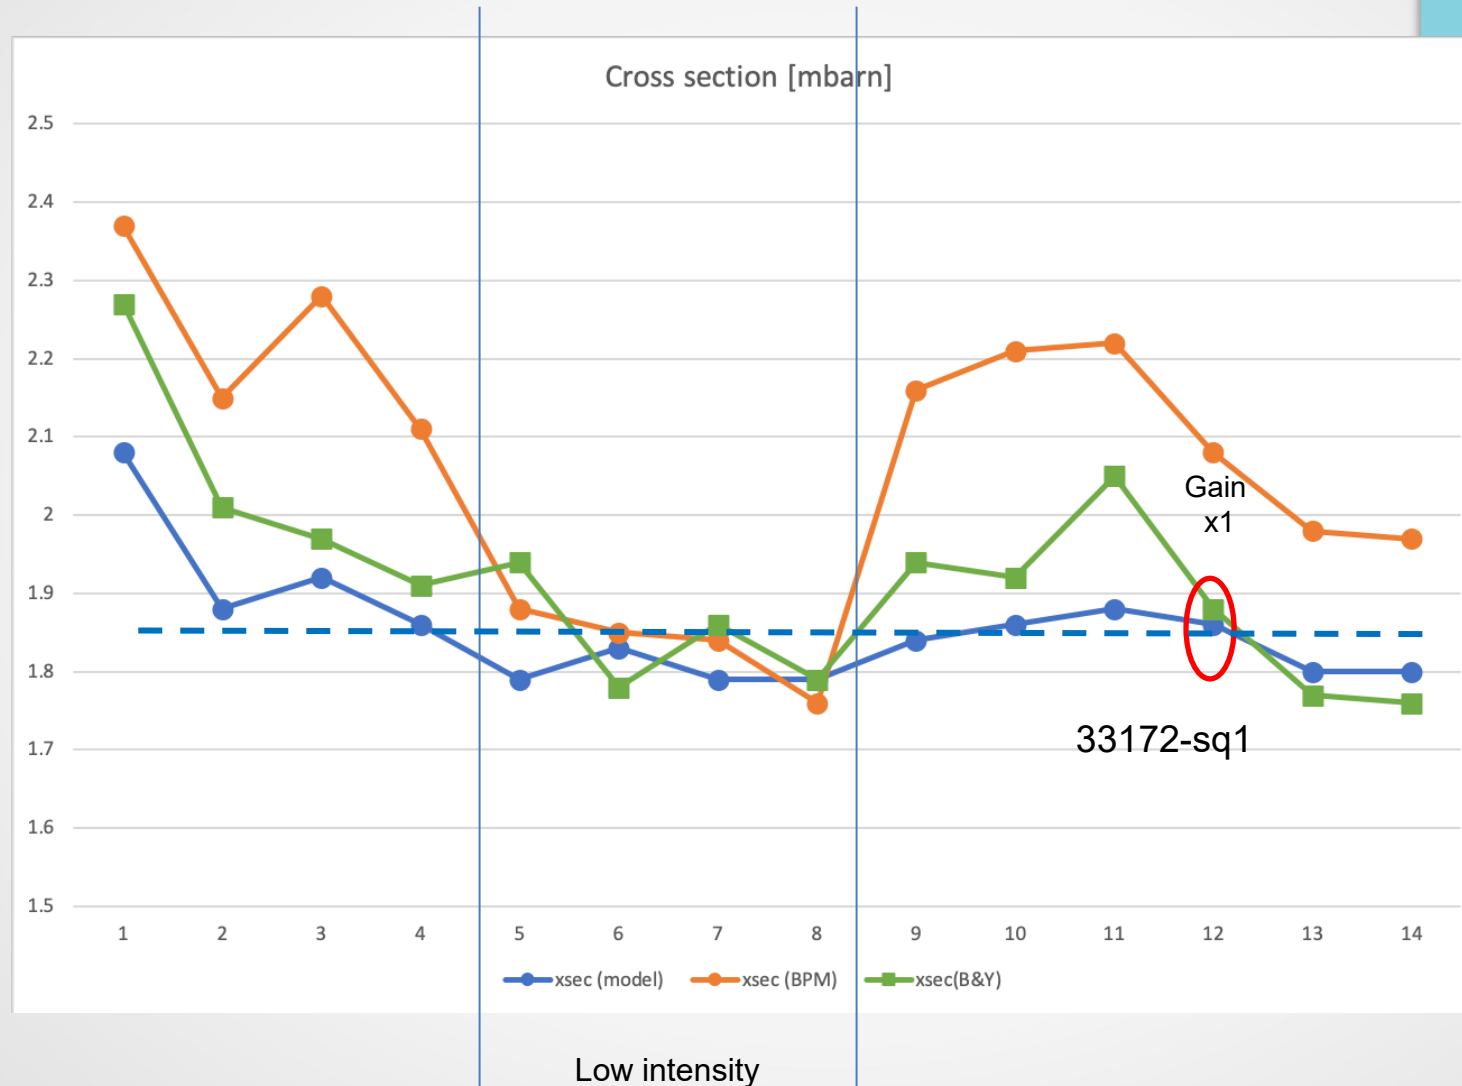

fixed

moving

Combine east&west

Low intensity: likely electronic cross talk  
High intensity: Beam-beam

# ZDC effective cross section pp22-255GeV

Cross section should be constant regardless of beam conditions

# summary

Cross section should be constant:

Only using “set” values satisfies this ‘rule’

Compare with independent measurement (IPM):

“set” values give best agreement with IPM

Rampfile does not appear to matter

Low intensity stores:

No apparent beam-beam

“set” and BPM agree within 5%

Using both rings more ‘random’

BPM vs “set” consistent with beam-beam

Intensity dependent

Electronic cross talk and beam-beam evident

Using both rings AND correct gain gives best agreement also for high intensity stores (need to work on understanding gain calibration)

Conclude:

Keep using “set” values

Avg. of 1.86 mbarn
